

**Review of the Draft Work Plan Radiological Survey and Sampling  
Former Hunter's Point Naval Shipyard,  
San Francisco, California, February 2018**

**GENERAL COMMENTS**

1. The approach proposed in the Work Plan Radiological Survey and Sampling, Former Hunter's Point Naval Shipyard dated February 2018 (Work Plan) is insufficient to protect public health and the environment. The site has a history of radiological activity on the site, and the radiological data evaluation has found widespread signs of falsification and data quality concerns in all parcels. Given these conditions, the actions proposed in the draft Workplan would not be sufficient to allow EPA approval of property transfer of any parcel. Far more extensive sampling and analysis needs to be done to address potential exposure to workers and future residents due to the uncertainty regarding the potential extent of contamination. The Work Plan provides the outline of an investigation of the former Hunter's Point Naval Shipyard (HPNS) that considers the Historical Radiological Assessment (HRA) as the primary basis for development of the sampling strategy and relies on assumptions that data obtained from the sampling of trench unit surface soils can be used to represent subsurface conditions. However, neither of these sources of information can be relied on solely for defining the parameters of the investigation because additional information about the site history and previous investigations have become known since the HRA was published. For example, data obtained from the sampling of trench unit soils is unreliable due to allegations, and in some cases proof, of sample collection fraud, improper sample and document custody/controls, and data manipulation. In addition to these confounding factors, a general failure to follow Work Plans by the previous contractor, as well as poor data quality associated with the previous investigation at the site suggests that the previous data is unusable. Further, information that demonstrates the presence of significantly radioactive objects such as deck markers, has been identified at various locations at the site which were not accounted for in the previous site conceptual model. As such, the Work Plan should be revised to provide a sampling strategy that considers the additional site history information, allegations of fraud, lack of work control, insufficient data quality, and new information about site conditions that differs from what was documented in the original investigation. The Regulatory Agencies have offered a suggested path forward on the investigation as Attachment 2, which should be considered in the revision of the Work Plan.
2. The Conceptual Site Model (CSM) presented in the text and Table 2-1 of the Work Plan does not provide a sufficient identification of the following sources of contamination and/or site conditions as follows:
  - a. The table in Potential Historical Sources of Radiological Contamination section should include radium paint as a potential source.

- b. The third bullet point under the Site Operations and History section should include specific details regarding the manufacture and use of radiography and calibration sources.
- c. The Radionuclides of Concern discussion on page 2-6 identifies Plutonium-239 as only associated with the Navy Radiological Defense Laboratory (NRDL) building 529, and the HRA Table 5-1 indicates Pu-239 was only present in solid sources. However, according to the Atomic Energy Commission (AEC)-issued Special Nuclear Material (SNM) License-35 for the HPNS, the Navy also possessed up to two-thousand (2000) grams of Pu-239 and fifty-five (55) grams of Plutonium-238 (Pu-238). The Navy has indicated in previous responses to comments that this material was used in Building 815. In addition, the HRA lists Pu-239 as a radionuclide of concern (ROC) in numerous other buildings and areas (e.g., Buildings 103, 113, 140, 142, Dry Docks 5, 6, and 7, etc.) Therefore, the analysis of Pu-239 should not be limited to the former Building 529 Storage Vault or to locations where Sr-90 was detected since both Pu-239 and Pu-238 are a concern at multiple locations. The Work Plan should be revised to include a requirement to analyze for Pu-239 and Pu-238 in all areas that may have been impacted by activities in or near Building 529, Building 815, areas where the HRA indicates Pu-239 is a concern, or any other areas where Pu-239 and Pu-238 may have been used.
- d. The table in Radionuclides of Concern section should include a list of all radionuclides used for making contaminated source materials and all other potential radionuclides that may be encountered above background concentrations.
- e. Under the first bullet point and fourth dash of the Uncertainties section, the phrase “and radionuclide decay” indicates the decay will alter concentrations of radionuclides at the site, adding to the uncertainty regarding the levels of such contamination at the site. However, the main ROC at the site is Ra-226, which has a half-life of 1600 years and as such will not have decreased significantly due to decay since site operations began. The table should be revised to remove the phrase “and radionuclide decay.” Alternatively, the text could specify that radioactive decay will impact the concentrations of shorter-lived radionuclides such as Sr-90 and Cs-137, but will not significantly affect the longer-lived radionuclides such as Ra-226, or uranium and plutonium isotopes.
- f. The Uncertainty discussion claims that all known sources of contamination were removed; however, there are allegations that “hot” samples were returned to trenches and evidence that some areas have buried radiological devices, such as areas associated with use of dredge materials as fill to construct land in Parcel D-1. In addition, previous investigations have identified the presence of radiological devices with significant radioactive material at the site. One such example includes the device detected outside a drain line near Building 205. The CSM statement that all known sources of contamination at the site have been removed does not accurately reflect site conditions. Please modify this statement to represent site conditions more accurately with respect to the listed uncertainties in the CSM.

- g. The Uncertainties discussion states that low-level radiological waste (LLRW) bins were tested by the Navy's independent waste broker at an offsite laboratory using 5-point composites, and only 3 out of 1,411 bins had results with Ra-226 above the release criteria. The Uncertainties section includes this condition as a fact supporting a hypothesis that there is a lower potential for radiological contamination to exist at the site than what is reported in the HRA. However, collection of random samples from large bins of waste soil would likely have missed most of the radiological contamination, which would have been present in small pockets in LLRW bins due to the practice of excavating 1 foot of soil surrounding any hot spot or radiological device and disposing of that soil as LLRW. The Work Plan CSM should be revised to modify the conclusion.
  - h. The fourth bullet point in the Uncertainties discussion should be reworded to state that Cs-137 and Sr-90 are present at HPNS because of Navy operations, as well as global fallout from nuclear testing or accidents. In addition, because of backfill activities, the presence of Cs-137 and Sr-90 from fallout and Navy activities are not necessarily found only on the surface. The table should indicate that Cs-137 and Sr-90 could be distributed throughout the surface and subsurface soil at HPNS.
  - i. The section on potential risk to human receptors does not include an evaluation of the cancer risk to potential receptors. The text in this section of the table only includes exposure pathways, but there is no evaluation of risk or discussion of the inputs needed to determine the risk from a reasonable maximum exposure (RME) to an individual for any exposure scenario (resident or otherwise).
3. Section 1.1 (Radiological Data Evaluation Findings) states on page 1-2 that based solely on a review of data previously collected by Tetrattech EC Inc. (TtEC), survey units will be divided into three main groups which include no action, re-analysis of archived samples, and confirmation sampling. However, these options appear to be based on assumptions that are not supported by the current Conceptual Site Model (CSM) uncertainties, which include various and extensive methods of data collection and reporting fraud committed by the previous site contractor TtEC, lack of work control, and large-scale data quality problems. Given these factors, none of the previously collected samples or data reported by the Navy's former contractor TtEC should be considered usable for decision making at the site and this data should not be used as such. Therefore, all areas of land still owned/occupied by the Navy will need to have newly generated supportable data for assessing compliance with the Record of Decision (ROD) release criteria. In addition, previous EPA comments on radiological data evaluation findings reports have stated that the re-analysis of archived samples cannot be relied on to produce defensible data and such data will not be accepted by EPA as valid for supporting decision making at the HPNS. Please revise the Report to remove all references to re-analysis of archived samples as a means to verify compliance with release criteria in accordance with the HPNS RODs.
4. Section 3.2 (Subcontractors) lists two laboratories, the Aleut Laboratory and the General Engineering Laboratory (GEL), will be used for this project; however, the text does not state

which laboratory will perform each of the proposed analyses or how the laboratories were determined to be qualified for such work. In addition, in accordance with EPA Quality System guidance provided in EPA QA/G-7, Guidance on Technical Audits and Related Assessments for Environmental Data Operations (EPA/600/R-99/080), technical audits and assessments of all activities related to data collection should be implemented to ensure that data collection is conducted as planned and data of the type and quality specified in project planning documents (i.e. Sampling and Analysis Plan, Quality Assurance Project Plan and associated Work Plans) is produced. As such, the laboratories performing analyses as part of the HPNS investigation should be audited prior to the start of the project. Please revise the Work Plan to clarify the responsibilities of each listed contract laboratory and to include a requirement that the laboratories will be audited by the Navy prior to the start of sample collection. In addition, the Work Plan should note that the regulatory agencies will also conduct their own independent audits/assessments of laboratory operations.

5. Section 4 (Survey Design) states that soils areas will be surveyed in accordance with their potential to be radiologically impacted, which include sites with known historical contamination, impacted sites with lower contamination potential, and background areas. These three main groupings of soil areas do not acknowledge that there are soil areas for which falsification of sample results have been alleged to have occurred. It is important that the Work Plan acknowledge the data falsification allegations since this condition defines the need to re-sample and should inform the development of the task specific plans (TSPs). Please revise Section 4 to incorporate information about the allegations so that the survey design fully reflects the range of site conditions in order to ensure the sampling plan/TSPs meet all of the data needs for the project.
6. Section 4 (Survey Design) discusses the identification of survey locations within buildings but does not address the specifics of classification of survey units. In accordance with guidance provided in the Multi-Agency Radiation and Site Survey Investigation Manual (MARSSIM) classification definitions, all survey units where remediation was previously completed and any areas where known or suspected data falsification occurred should be classified as a Class I survey unit.
7. Section 4.3.1 (Soil Area Groups) indicates Group 2a soil includes the collection of surface soils, which are considered mixed and homogenous. However, in many areas at the HPNS, the surface was graded for drainage and additional import fill was brought in to fill low spots (i.e., the surface has been changed). The Work Plan does not state how import soil used to fill low spots prior to placement of the durable cover will be identified. As such, former trench locations will need to be identified and inspected visually so that any import fill can be removed in order to ensure surface gamma scans are representative of the original soil surface of the trench unit to the greatest extent possible. Please revise the Work Plan to include this information and address this concern.
8. Section 4.3.1, Soil Area Groups, states on page 4-17 that surface soils from trench units with one hundred percent native back fill, defined as Group 2a soils, is representative of Group 2b soils. However, the assumption that trench unit surface soils are representative of subsurface conditions/soils is not defensible based on the numerous allegations of worker fraud and data

manipulation that occurred during site investigation and remediation activities between 2006 and 2015, and other factors as follows:

- Numerous and extensive allegations of worker fraud with respect to sample substitution, falsification of sample custody records, data reporting manipulation, and others indicate that previous data regarding site conditions is not reliable or usable for decision making. For instance, these allegations include sample substitution, failure to investigate anomalous elevated gamma scan readings for both surfaces and excavated soil scanned at the radiological screening yards and placed back in trenches, and data manipulation. Therefore, the surface soils of trench units cannot be assumed to be representative of subsurface trench unit soil.
- Group 2b soils include soils not removed during previous excavations. Analysis of trench unit surface soils that have been removed, mixed with one or more other trench unit fill materials and replaced in trenches cannot be considered representative of soil that was not previously removed.
- Group 2b soils include those soils obtained from former building sites or surface soils from beneath building crawlspaces. Neither of these Group 2b soils are represented by other Group 2a data, and therefore, both will require investigation based on an independent assessment of the sampling needed to be representative of site conditions.

Please revise the Work Plan to remove references to the assumption that Group 2a soils are representative of those soils defined as Group 2b, including subsurface trench unit soils, and former building sites or crawlspace soils from beneath current buildings.

9. Section 4.3.2 (Size of Survey Units) states that on an area basis, the standard MARSSIM sizes of survey units include Class 1 land areas up to 2,000 square meters ( $m^2$ ); Class 2 land areas 2,000 – 10,000  $m^2$ ; and Class 3 land areas with no limit; and that the actual sizes of will be provided in TSPs. The Work Plan does not specify how the size of the Class 3 survey units (SUs) will be identified or what factors will be considered in determining how large the Class 3 SUs may be. Additionally, the Work Plan does not state what, if any restrictions will be placed on grouping SUs together into a single Class 3 SU. Please revise the Work Plan to address this concern.
10. Section 4.3.3 (Number of Samples in Survey Unit) and Table 4-3 (Number of Samples in a Survey Unit) includes the parameters used to calculate the required number of samples needed for Class 1 Survey Units, however neither the table nor text in Section 4.3.3 state how the uncertainties associated with the release limits listed in Table 4-3 were determined. In addition, please explain how the uncertainty values associated with background reference areas compare to the variance associated with measurements in the contaminated areas and provide a justification for which variance was selected (i.e., variance from reference areas versus contaminated areas) for use in the MARSSIM calculations.
11. Section 4.3.3 (Number of Samples in Survey Unit) does not provide sufficient justification to support a conclusion that collection of eighteen samples in the reference area and survey

units is sufficient to support a 99% statistical confidence in the outcome of the hypothesis testing used in the Wilcoxon Rank Sum (WRS) test. The Work Plan uses MARSSIM equation 5-1 for determining the number of samples required for the WRS test, and selects a value for variance ( $\sigma$ ) of 0.28 for Ra-226 and of 0.033 for Cs-137 based on some portion of the total number of background data points. However, according to MARSSIM guidance, when the standard deviation of sample results in the reference area and the survey unit are different, the larger of these two values should be used to calculate the relative shift so the number of samples is sufficient to meet the assumptions of the statistical test. In this case, since site investigation sample data is not available, it seems appropriate to select a larger variance since it would be likely that site sample results will have a higher variability than background data. From review of the background reference area data sets provided by the Navy for Parcels A, B, C, D-1, and D-2, the largest variance ( $\sigma$ ) for Cs-137 was identified as 0.0498 picoCuries per gram (pCi/g) from the off-site laboratory measurements from Parcel B. The largest variance reported for Ra-226 was identified as 0.479 pCi/g from the off-site laboratory data, also in Parcel B. Using the remaining parameters selected in the Work Plan which include confidence levels of 99% (i.e., alpha ( $\alpha$ ) and beta ( $\beta$ ) error of 0.01), and a delta ( $\Delta$ ) of 1 for Ra-226 and 0.113 for Cs-137, the calculated number of samples ( $N/2$ ) required to be collected considering the 20% increase in number of samples recommended by MARSSIM is 25 per on-site SU and per background reference area for Ra-226, and 21 per on-site SU and per background area for Cs-137:

$$[ \text{QUOTE} ] * 1.2 = 48.766 \approx 50 = N$$

$$\text{Therefore } [ \text{QUOTE} ] = 25$$

In addition, the following two considerations should be kept in mind during the site investigation process, as follows:

- It is possible that the variance for site investigative samples is higher than currently reported for background samples. For example, twenty Final Status Survey systematic samples collected in Parcel G, Trench Unit 70 on December 3, 2007 indicate the variance associated with the Ra-226 results is 0.72 pCi/g. Using equations from Chapter 5 of MARSSIM and calculating the number of samples required to be collected using a variance of 0.72 at the 99% confidence level gives a value for 'N', (total number of samples) of 62.8. With a 20% increase in samples (13 samples in this case) to account for lost samples, rejected data, etc., results in a total of 76. Dividing the 'N' value in half and rounding up to a whole number results in a value of 38, indicating 38 samples are required to be collected in the reference area and 38 samples need to be collected in each SU. As such, a re-calculation of the required number of samples needed to demonstrate the statistical confidence in the WRS test has been met will be required to be performed if site investigation sample data result in a variance greater than the 0.479 for Ra-226 or 0.0498 for Cs-137.
- It is noted that since the HPNS ROD requires compliance with a "not to exceed" release limit; therefore the final data set and reports generated by the Navy will need to demonstrate that all sample results are below the release criteria. If any of the data are above the release criteria, data should be provided to demonstrate that the elevated levels

were determined to be due to Naturally Occurring Radioactive Material (NORM), or that the location of the exceedances were remediated/removed from the survey unit.

Please revise Section 4.3.3 to address these concerns and to include a requirement to select 25 as the required sample size for the initial investigations of survey units and background reference areas. If data generated under the HPNS Sampling and Analysis Plan (Field Sampling Plan and Quality Assurance Project Plan) Radiological Data Evaluation and Confirmation Survey issued June 2017 [Master SAP] and future approved TSPs indicate a reduced variance, sample size calculations may be performed to re-calculate the required number of samples.

**12. [John, This confused me, but I got this clarification this morning:**

From Jana: I will clarify the comment – I was intending to clarify two items:

- 1) I was intending to question the Navy about why they would call the WRS test, a 'DCGLw test'. It is confusing in the Work Plan to use different terms for the WRS test, so the comment is basically saying it is not acceptable to provide confusing terminology in the WP and for clarity, it should be changed to only use the WRS test terminology.
- 2) The comment is also intended to clarify that even though they are selecting the sample size based on the WRS test, the final release for a SU will be based on a 'not to exceed' release limit and the FSS results must demonstrate that no result exceeds the ROD release criteria (even though technically MARSSIM and use of the WRS test would allow one or more results to exceed the release criteria if the WRS statistical test indicated the SU as a whole does not exceed the release criteria by comparing the median of the SU to the median of the background data set).]

The fifth bulleted item in Section 6 (Data Evaluation) and Figures 6-2 (Group 1 Soil Data Evaluation Process) and 6-3 (Group 2 Soil Data Evaluation Process) indicate that the Derived Concentration Guideline Level for the wide area (DCGLw) test will be used to evaluate sample results for compliance with release criteria. However, it is unclear why the Work Plan refers to the DCGLw test instead of the WRS test or how the WRS test results will be used to meet the goals of the project since the objective of the WRS test is to demonstrate compliance through a comparison of sample population estimators, (i.e., the median of the survey unit data compared to the median of the background data) rather than to demonstrate individual results meet a 'not to exceed' remedial goal as specified in the HPNS ROD. Please revise the Work Plan to address this concern.

- 13.** Section 6.6.1 (NORM Evaluation) proposes analyzing Uranium-238 (U-238), Uranium-235 (U-235) and Thorium-232 (Th-232) by alpha spectroscopy and Ra-226 by radon emanation in order to perform a Naturally Occurring Radioactive Material (NORM) evaluation for radionuclides with concentrations above the release criteria. Figure 6-4 (NORM Evaluation Process) on page 6-8 includes a formula for use in evaluating whether elevated concentrations of certain radionuclides are considered part of NORM or represent site contamination. However, a reference for use of this equation as scientifically supported has not been provided in the Work Plan. Also, the Work Plan does not propose an evaluation of whether the individual radionuclides in the U-238 or Th-232 decay series are in equilibrium.

Additionally, the value obtained using the equation may be subject to interpretation given that the results for U-238, U-235, Th-232, and Ra-226 at such low concentrations will have an uncertainty associated with those results which cannot be accounted for in the formula and which may alter the outcome of the test. It is unclear why this approach is proposed in the Work Plan versus the approach proposed by EPA, which is to analyze Uranium isotopes U-234, U-235, and U-238 and Thorium isotopes Th-234, Th-230, Th-232, and Th-228 by alpha spectrometry in addition to the gamma spectroscopy analysis in order to identify whether parent and daughter radionuclides are in secular equilibrium for purposes of differentiating background versus site-related contamination in soils. In addition, providing the analysis of parent and daughter radionuclides from the Uranium-238 decay chain will help substantiate the results obtained for Ra-226 by radon emanation analysis. If after a certain number of samples have been analyzed, it is determined that providing only the results for U-238 by alpha spectrometry and Ra-226 by radon emanation is sufficient for identifying whether levels of primordial radionuclides in samples are present in secular equilibrium, or are present at elevated levels that indicate site contamination, consideration may be given to reducing the analytical requirements. Please revise the Work Plan to require that all reference area samples and site investigation samples requiring a NORM evaluation, be analyzed by alpha spectrometry, including uranium isotopes U-232, U-234, U-235/236, U-238, and for thorium isotopes Th-234, Th-230, Th-232, Th-228, and Th-227, and to include the reporting of the additional isotopes by gamma spectroscopy.

14. Table 4-1 (Radionuclides of Concern) indicates that Potassium-40, Thallium-208, Bismuth-212, Lead-212, Bismuth-214, Lead-214, Radium-223, Radium-224, Thorium-227, Actinium-228, Protactinium-231, Protactinium-234, and Protactinium-234 metastable will be reported in the gamma spectroscopy analysis. Given the history of NRDL activities, which includes the possession of up to two thousand grams of Pu-239 and 55 grams of Pu-238, the gamma spectroscopy (gamma spec) analysis also should include the reporting of Americium-241 (Am-241) in order to provide a screening for special nuclear material radionuclides such as plutonium. Further, all gamma-emitting radionuclides detected should be reported and the raw laboratory data should be provided that includes any unquantified gamma photopeak energies. All soil gamma spectroscopy analysis should be performed on an N-Type high purity germanium detector in order to quantify the lower energy radionuclides that have gamma photopeaks below 100 kiloelectron volts (keV) (i.e., such as Americium-241). In summary, the Work Plan should be revised to include the reporting of all potential radionuclides by gamma spectroscopy, and should also provide the sample specific Minimum Detectable Concentration (MDCs) per nuclide, as follows:

- Gamma Nuclides requiring Sample Specific MDCs:
  - Am-241, Cs-137, Co-60, Eu-152, Eu-154, K-40
- Uranium (U-238) Series Nuclides by Gamma Spec
  - Pa-234m, Ra-226, Pb-214, Bi-214, Pb-210
- Thorium (Th-232) Series
  - Ra-228/Ac-228, Ra-224, Pb-212, Bi-212, Tl-208

- Actinium (U-235) Series
  - Pa-231, Th-231, Th-227, Ra-223, Pb-211
- Since Am-241 is a contaminant of Pu-239, if Americium-241 is detected in any of the samples, the sample should be then also be analyzed for plutonium isotopes by alpha spectroscopy.

Please revise the Work Plan to include the gamma spectroscopy analysis of the bulleted list of radionuclides and to provide the associated MDCs for each radionuclide. Please also report any peaks, which the gamma spectroscopy radionuclide library identifies as a specific radionuclide.

15. It is imperative that the TSPs include all of the site-specific quality assurance requirements not specified in the Master SAP. TSPs should be provided in the Uniform Federal Policy Act Quality Assurance Project Plan (UFP-QAPP) format to ensure all implementing technical and quality requirements for sample collection, analysis, reporting, validation and quality assessment are documented for each site being investigated. Please provide TSPs in the UFP-QAPP format to ensure that all necessary site-specific quality assurance requirements are included.
16. One of two approaches should be taken to evaluate whether detected radionuclides are naturally occurring. Background reference areas may be identified for collection of new background samples. Alternatively, instead of developing new background numbers, existing background numbers could be used for comparison to site investigation samples. Then, for all samples that exceed the existing background plus the remedial goals (RGs) in the Record of Decision, e.g., in the case of Ra-226, sample results that exceed 1 PCi/g over background, a gamma and alpha spectroscopy analysis for the full list of Uranium and Thorium isotopes listed in the previous comments should be completed to evaluate whether all of the detected primordial parent and daughter radionuclides are in secular equilibrium. In this case, the background number developed for Cs-137 on Parcel E-2 could be used. [Attach Christina's table of existing background numbers for reference]
17. Section 4.2.1 (Soil Reference Areas) indicates that new background samples will be collected at the same locations previously used for collection of background samples and will include sampling surface and subsurface soil at various depths. However, there are several issues regarding the selection of the appropriate background reference areas that should be considered:
  - The Work Plan should state if the proposed background locations are known to be locations where the land was built up from soils originating at different locations. The Work Plan and/or forthcoming TSPs should specify whether the areas selected for background measurement collection were built from imported soils originating from different locations, and if the selected background areas remained undisturbed by site operations.

- The text states background samples will be collected at various depths and that surface and subsurface background samples will be collected, but does not state if depth-specific background values will be obtained and evaluated.
- Background samples should not be collected from locations where import fill was placed. This includes locations of former trenches/excavations for any remedial or removal action and areas where import fill was placed as surcharge, e.g., to improve drainage as part of installation of the durable cover.
- Section 4.2.1 indicates that all Ra-226 values for all depths and locations will be averaged together to obtain one value as the background concentration; however, Section 6.6 (Background Evaluation) states there is not a single, consistent radiological background at HPNS that can be used for evaluating all survey results because much of the land mass was obtained by using various soil types from different sources/locations. Section 6.6.3 (Regional and Local Background Evaluation) states “[W]hen the existing background reference area data set is not considered representative of background, it may be possible to identify a new background reference area to provide a local background that supports evaluation of local data. It may also be possible to identify a regional background based on scientific research at nearby sites, or radiological studies performed at neighboring sites.” The text in Sections 4.2.1, 6.6, and 6.6.3 should be reconciled and revised to provide consistent information. Alternatively, the Navy should analyze background samples, as well as any site samples with remedial goal exceedances for the full list of uranium, and thorium parent/daughter isotopes by alpha spectroscopy, as well as the full list of gamma spectroscopy radionuclides listed in this set of comments. The results of such analyses can be used to identify whether primordial radionuclides are in secular equilibrium for determining whether soil samples with concentrations exceeding release criteria represent background concentrations, or if elevated concentrations are due to site contamination.
- Section 4.2.1 states that a minimum of 150 soil samples will be collected from at least five locations to represent background based on MARSSIM and NRC criteria. However, since the HPNS site was built using soils from different locations with different compositions, it is unclear how providing one general background number for each radionuclide to represent background across the entire HPNS site is defensible.
- The location for Parcel C background sampling should not be near the former location of the on-site rad lab (Figure 4-1 proposes the sampling location in this area).
- It is unclear if the Parcel B location is unimpacted or if import fill has been placed in this area. More information about this location should be provided.
- Parcel D-1 location is near an area where numerous rad devices were found on the surface; therefore it is unclear if this location is unimpacted.
- The Work Plan does not explain how multiple fill types will be handled in the assessment of identifying the appropriate locations to sample for background.

- Both the surface prior to sampling and cores/samples should be scanned to ensure that background samples do not include any “hot spots” or soil adjacent to buried rad devices.
- If Black Beauty sand blast grit is encountered at a background sample location, it should not be sampled. Black Beauty sand should be excavated for off-site disposal.
- Sand from Site 518 should be sampled to determine if it is in secular equilibrium. If it is in secular equilibrium, enough samples should be collected to constitute a separate data set for comparison to other fill sand. However, if other fill sand has different radiological characteristics, it may not be appropriate to use Site 518 sand data for comparison.
- Similarly, background could be biased high if samples are collected from granite. There is evidence that crushed granite from the Sierras was used as backfill in some areas of the site. Crushed granite was identified definitively at IR 07/18 and may have been used in other areas. If crushed granite is found, background samples should be segregated for consideration for unique background numbers that would only be used in areas where granite is identified. Note that granite is not a rock type in the Bayview/Hunters Point Area, so samples of granite should be excluded from site-wide background.
- Reference areas should receive a gamma scan prior to collection of samples. Samples should not be collected from gamma scan hot spots to minimize the chance of including contaminated soil and/or radiological devices in the samples.
- If acceptable background areas are identified, the reference area should be scanned to ensure that there are no "hot spots" before any samples are collected. Samples should also be scanned before they are submitted for analysis. Scanning should be performed for both gamma and beta emitters to identify any locations that may have been contaminated by site operations. Beta scanning should be included to ensure Strontium-90 is also not present. If elevated beta radiation is detected, the sample should not be included in the background data set.
- For each reference area sample, both gamma spectroscopy and alpha spectroscopy should be run for the full list of radionuclides listed in the previous comments to evaluate whether the primordial radionuclides in these samples (i.e. Th-232, U-238, and U-235) are in secular equilibrium with the daughter products. In addition, if Am-241 is detected in the gamma analysis, the sample should not be included in the background data set.

Please revise the Work Plan and/or forthcoming TSPs to address these questions and concerns.

18. Section 4.3.1 (Soil Area Groups) proposes to group all survey units not selected as Group 2a, into a broad Group 2b category, which will be investigated as MARSSIM Class 3 survey units and will receive random and biased soil sampling only. However, a defensible basis for the selection of such Group 2b areas is not provided in the Work Plan and does not appear to

consider that previously collected data at these areas are not reliable for supporting any assumptions or decisions at the HPNS. Please revise the Work Plan to provide a more area-specific strategy that considers all historical, environmental/location specific factors, as well as recent revelations regarding the lack of integrity in previous data collection, and which incorporates the regulatory agencies suggested path forward for identifying the sampling strategy.

19. Survey unit sizes should not be modified from those used during the original remediation. MARSSIM requires that locations with known contamination be considered Class I survey units. Survey units where contamination is suspected are Class II survey units. Since contamination was found in most of the original survey units and is suspected in others due to the types of alleged falsification, there are no survey units that can be considered Class 3 survey units. It should be noted that it cannot be assumed that all of the contamination detected and remediated during the original trench and building site excavations was false positives. For example, the Ra-226 concentrations in some samples sent to the off-site laboratory exceeded the cleanup criterion of 1 pCi/g over background; since samples with elevated Ra-226 concentrations were not sent for off-site analysis while the on-site laboratory was operational, the on-site laboratory results were actually false negatives. Also, it is known that Cs-137 was used by the Navy Radiological Defense Laboratory (NRDL) for numerous purposes and that Cs-137 was found at elevated levels in Buildings 313, 313A, 351A, 364, and 366, and in associated piping, and manholes. Both the Gun Mole Pier and the peanut spill were remediated due to elevated Cs-137. Further, due to quality assurance problems in the on-site laboratory, most Cs-137 results were at or below zero, indicating that when Cs-137 was detected, it was not a false positive. For these reasons, if contamination was found in piping or in any samples, it should be considered real and the associated trench units or building sites, as well as downstream trench units, should be considered Class I survey units and the size of these survey units should not be increased. Please revise the Work Plan to state that the original survey unit sizes will be unchanged.
20. Section 4.5 (Data Quality Objectives) does not address all of the identified data needs for demonstrating the site meets the remedial goals as specified in the HPNS ROD. These additional objectives include investigating areas at the site where the allegations were made about data falsification and manipulation are alleged or have been proven to have occurred, to address areas where there was a lack of adherence to Work Plan instructions, and to include consideration of the presence of radiological objects remaining at the site, as well as all of the uncertainties for the CSM. Please revise the Work Plan to include more comprehensive Data Quality Objectives to be utilized to define the nature and extent of any contamination to address the additional uncertainties with respect to site conditions.
21. Section 4.7 (Radiological Laboratory Analysis) states that site investigation soil samples will be analyzed for Cs-137 and Ra-226 by gamma spectroscopy analysis. In addition, this section states ten percent of the soil samples will also be analyzed for Sr-90 or total strontium by a gas flow proportional counter in accordance with the Master SAP, and if other ROCs are identified in the TSP, analyses will be performed for the additional ROCs. Some additional clarifications about these requirements are requested and include the following:

- It is noted that the Work Plan proposes analyzing site investigative samples for Ra-226 by gamma spectroscopy initially, as opposed to using radon emanation as is proposed for analysis of background reference area samples. The Work Plan should require a demonstration that the two analysis methods (gamma spectroscopy and radon emanation) are comparable prior to implementing site and to ensure that the MDC for Ra-226 falls below the release limit for both radioanalytical methods.
- The required laboratory analyses do not indicate how the gamma spectroscopy data will be reviewed to determine if additional analyses should be conducted. For instance, if Am-241 is identified in the gamma analysis, the sample should then also be analyzed by alpha spectroscopy for plutonium isotopes because Am-241 is a contaminant of plutonium. The Work Plan and forthcoming TSPs should include data decision rules for detection of all potential ROCs, and refined by area-specific history/knowledge.
- Samples should be screened in the field for radioactivity for both gamma and beta emitters. The Work Plan should include this requirement.

Please revise the Work Plan to address these bulleted items.

22. Section 5.2.2.3 (Group 2b Trench Unit Surveys) states that for group 2b survey units, core samples will be collected and scanned for gamma emitting radionuclides. While gamma scanning can identify elevated radiation levels from ROCs that are gamma emitters, some of the ROCs are not identifiable by gamma scanning, including those that are primarily alpha or beta emitters. For instance, site history included the use of Strontium-90 which is a pure beta emitter, therefore gamma scanning would not detect the presence of this radionuclide. Therefore, the Work Plan should be revised to also require scanning of core samples for beta radiation. Further, it is expected that for any core samples sent for laboratory analysis, that the gamma spectroscopy analysis include the quantification of Am-241, if present. A positive result for Am-241 would indicate other alpha-emitting radionuclides are most likely present. As such the Work Plan should then require that alpha spectroscopy analysis be completed to quantify any plutonium and thorium isotopes that may be present. Please revise the Work Plan to include a requirement to scan core samples for the presence of elevated gross gamma and beta radiation, and to ensure laboratory analyses of core samples include the identification of Am-241 if present, as an indication that other alpha-emitting radionuclides may be present.
23. All references to the Nuclear Regulatory Commission's (NRC) Regulatory Guide 1.86 (Reg Guide 1.86] should be removed since it was recalled by the NRC. Please revise the Work Plan to remove these references to Reg. Guide 1.86.
24. The listing of soil volumes throughout the Work Plan should be provided in metric units in order to provide consistency with the MARSSIM guidance references so that compliance with MARSSIM guidance is more clearly demonstrated. Please revise the Work Plan to address this change.

25. All import backfill should be sampled for chemical and radiological constituents prior to transporting it to the site. If any concentrations exceed background or cleanup goals, the soil should be rejected for use as backfill. Please revise the Work Plan to require sampling and analysis of import backfill to determine if it is suitable for use at HPNS.
26. Database “fields definitions” should be included in the work plan including instrument and analytical specific fields identified. (i.e., Date/Time, Count time, sample volume, MDC, result, uncertainty, etc. are included on paper forms and electronic data deliverables.)
27. The Work Plan does not reference the Master SAP or discuss the role of Regulatory Agency involvement/oversight for the site investigation at HPNS. EPA will continue to partner with the Navy and the State of California in the site investigation process. As such, the EPA will be involved in the following actions: independent oversight of field activities; conducting laboratory and/or field audits, requesting split samples for independent analysis, and independent data review/validation of some portion of the data generated during the forthcoming investigation. As such, please revise the Work Plan to require ten percent (10%) split sampling for every survey unit sampled for analyses by another laboratory for quality control purposes.
28. The Work Plan and Master SAP provide the outline for the forthcoming TSPs which should include more specific detailed plans. For consistency with EPA quality assurance guidance and quality program policy, please ensure the following requirements for the project are met:
- An agreed upon, the final QAPP/Master SAP and TSPs will be needed to be provided to the regulators prior to the review of the Contractor Supplied SOPs to ensure compliance.
  - Field audits and contractor lab audits should be performed by the Navy to ensure compliance with the QAPP, SAP, SOPs. The regulators will also perform their own independent audits and assessments.
  - It is noted that the Work Plan states that laboratories that have been certified and are compliant with the Department of Defense/Department of Energy (DoD/DOE) Quality Systems Manual for Laboratories version 5.0/5.1 of the DOD/DOE QSM will be utilized for sample analyses. Please ensure this requirement is also included in the Master SAP.
  - A discussion concerning potential laboratories will be needed after the QAPP/SAP and TSPs are finalized to optimize sample size collection, counting geometry used by the laboratory and counting times needed to ensure MDCs are met.
  - Soil gamma scan data will need to be collected with sub meter global positioning system (GPS) coordinates, and soil sample collections will need to include sub-meter GPS coordinates and hand measured sample collection depths.
  - The Regulatory Agencies will likely collect/analyze split samples.

- On-going communication between the Navy and regulators should continue frequently to discuss the nature and extent of contamination found while the survey unit investigation is ongoing.
- The sample specific required MDC for lab analyses shall be stated in the QAPP and are required to be less than or equal to 10% of the release criteria for all ROCs.
- Per previous HPNS Work Plans, 10% of all samples collected per survey unit will need to have Sr-90 specific analyses completed, and 100% of areas that require Cs-137 remediation shall also be analyzed for Sr-90.
- Currently, the Work Plan only includes calculations of the required Gamma Scan Speed based on the Ra-226 micro-shield exposure rate, which includes all of the gamma emitting progeny nuclides; therefore, Cs-137 would be the more limiting radionuclide for determining the scan speed. Scan speed determinations should be included individually for each ROC.

Please ensure the HPNS QAPP/Master SAP and TSPs include all of these requirements.

## **SPECIFIC COMMENTS**

- 1. Section 4.1.1, Release Criteria, Page 4-12 and Table 4-2, Project Release Criteria, Page 4-12:** Section 4.1.1 and Table 4-2 should include loose surface contamination release criteria in addition to residential soil, building surfaces, and equipment or waste surfaces. Additionally, Table 4-2 should be revised to include radionuclide daughter products with half-lives greater than 5 to 7 years and Pb-210, with detection limits defined in the quality assurance project plan (QAPP)/Master SAP. Please revise Section 4.1.1 and Table 4-2 to include these additional details.
- 2. Section 4.1.2.1, Soil Investigation Levels, Page 4-12 and Section 6.3, Evaluation of Scan Data, Page 6-5:** The second paragraph of Section 4.1.2.1 states the investigation level for gamma scan results will be established at three standard deviations above the mean for the gamma scan data set being evaluated. However, the ability to identify contamination is reduced if the investigation level is based on three standard deviations of the mean of the survey unit being investigated. Therefore, the Work Plan should be revised to state that for gamma scanning data, the investigation level will be established at three standard deviations above the mean for the gamma scan reference data set in lieu of “the gamma scan data set being evaluated.” Also, the appropriateness of identifying the investigation level as three standard deviations above the mean should be discussed in the Work Plan. Please revise Section 4.1.2.1 to state that gamma scan results will be established based on the gamma scan reference background data set. In addition, please revise the Work Plan to justify using a three standard deviation of the mean concentration as the investigation level.
- 3. Section 4.1.1.2, Building Investigation Levels, Page 4-13:** Alpha and beta static and scan measurement investigations should be based on scans conducted at reference background

areas. Please revise Section 4.2 to indicate that investigation levels will be based on scans of reference background areas.

4. **Section 4.2.1, Soil Reference Areas, Page 4-13 through 4-16:** Section 4.2.1 does not specify the minimum sample size that will be collected. Please revise Section 4.2.1 to specify the minimum sample size that will be collected.
5. **Section 4.2.1, Soil Reference Areas, Page 4-16:** The first paragraph discusses splitting samples but does not include information about the need to ensure the representativeness and comparability of the split samples analysis results. Samples should be homogenized before they are split. Alternatively, the full sample volume should be sent to each laboratory in sequence to avoid questions about reproducibility of results. Please revise the Work Plan to specify that the samples should be well homogenized before they are split or to specify that the full sample volume will be sent to each laboratory for analysis.
6. **Section 4.2.2, Building Reference Areas, Page 4-16:** The phrase “static measures” in the third paragraph of Section 4.2.2 should be replaced with “static measurements.” Please make this change.
7. **Section 4.3.1, Soil Area Groups, Page 4-17:** The same Survey Unit Numbering that was previously used should be carried over in this Work Plan. Additionally, a table should be provided to clarify the Soil Areas within a Survey Group, scan measurements, surface soil sampling, and core sampling numbers. Please revise Section 4.3.1 to clarify and discuss soil area groups and/or to ensure this information is included in the TSPs for each survey unit and parcel.
8. **Table 4-3, Number of Samples in a Survey Unit, Page 4-19:** Table 4-3 should include units (e.g., pCi/g) for Ra-226 and Cs-137. Please revise the table to include units.
9. **Section 4.6.1, Soil Survey Instruments, Page 4-22:** Section 4.6.1 should state that background will not be subtracted from gamma scanning instrument measurements during characterization. Please revise Section 4.6.1 to state that background will not be subtracted from gamma scanning instrument measurements during characterization.
10. **Table 4-5, Instruments and Investigation Limits for Static Measurements, Page 4-22:** Table 4-5 should specify the nuclide that was utilized to determine efficiency. Please revise the text to include the nuclide used to determine efficiency.
11. **Section 4.6.6.3, Instrument Beta Scan Measurement Rates and Alpha Detection Probabilities, Page 4-29:** Additional details should be provided regarding alpha/beta scanning instrumentation. Based on example calculations used for alpha/beta scanning instruments, it is unclear which instrument will be selected for alpha/beta scanning to meet data quality objectives (DQOs) and what scan speed will be selected. Please revise Section 4.6.6.3 and forthcoming TSPs to discuss additional details regarding instrumentation and scan speeds for alpha/beta scanning.

- 12. Section 4.7, Radiological Laboratory Analysis, Page 4-33:** Section 4.7 should also discuss additional analyses required, which may include uranium/thorium and plutonium/ameridium analyses by alpha spectroscopy. Please revise Section 4.7 to discuss requirements for potential additional analyses.
- 13. Section 5.1.2.1, Group 1 Trench Unit Surveys, Pages 5-2, 5-3, and 5-4:** The Work Plan does not account for the presence of gravel (asphalt base course) beneath asphalt or for the fact that in many areas, import soil was used to build up the surface to improve drainage prior to paving each parcel. After the asphalt has been removed, all asphalt base course, gravel beneath concrete, and import fill soil should be removed from the surface prior to gamma scanning and sampling to ensure surveys are representative of site conditions. Please revise the Work Plan to state that asphalt, asphalt base course, concrete, gravel, and import fill soil will be removed from the surface prior to gamma scanning and sampling.
- 14. Section 5.1.2.1, Site Preparation, Page 5-2:** An additional bullet point should be added stating that each task will be included in the TSPs. Please revise the text to add a statement indicating that all activities will be included in the TSPs.
- 15. Section 5.2, Surface and Subsurface Soil Investigations, Page 5-2:** For clarity, Section 5.2 should include a table that includes Group Areas, survey unit sizes, scanning requirements, surface sampling requirements, and core sampling requirements. Please revise Section 5.2 to include a table with investigation details.
- 16. Section 5.2.1.2, Group 1 Trench Unit Surveys, Page 5-4:** This section does not discuss whether gravel (asphalt base course or gravel beneath concrete surfaces) will receive a gamma scan. Similarly, there may be import fill beneath the asphalt base, which is not representative of the trench unit contents. Please revise this section to discuss the presence of the gravel and possibility of the presence of fill beneath the asphalt base so that information in the Work Plan is sufficient for developing a sound sampling strategy for collecting representative data from the trench units.
- 17. Section 5.2.2.2, Group 2b Surface Soil Surveys, Page 5-5:** This section states that surface soil at former building sites and in crawl spaces underlying existing buildings in Group 2b areas will be surveyed as Class 3 survey units. The durable cover generally consists of two or more inches of asphalt, and four inches of gravel (asphalt base course). However, there may also be an unknown thickness of import fill beneath the gravel (placed for grading to control drainage). All of durable cover and import fill beneath the gravel should be removed before surface scanning is conducted in order to ensure the gamma surface scans can achieve the calculated MDC for the target soils in accordance with the sampling plan. Please revise the Work Plan to specify that the durable cover and all import fill be removed prior to performing surface gamma scans.
- 18. Section 5.2.2.3, Group 2b Trench Unit Surveys, Page 5-5 and Figure 6-2, Decision Matrix for Soil Sampling, Page 6-4:** These sections of the Work Plan do not discuss how the location of a trench unit will be confirmed given that trench units will have a durable cover and possibly import fill material covering the units. Please revise the Work Plan to

include information about how the trench units will be located and also ensure that the durable cover and any fill material located under the durable cover be removed prior to performing any gamma scans.

- 19. Section 5.4.1, Building Surface Investigations, Page 5-6:** Section 5.4.1 should discuss data logging requirements, such as date/time stamp requirements and how alpha, beta, and gamma measurements will be recorded. Please revise Section 5.4.1 to include additional detail regarding data logging requirements for building survey unit measurements.
- 20. Section 5.5.4, Exposure Rate Surveys (Dose Rates), Page 5-8:** The phrase “subtracting an equivalent measurement” should be deleted from the first bullet point of Section 5.5.4. Please make this change.
- 21. Section 6.4, Evaluation of Sample Data and Static Measurements, Page 6-6:** The mean, median, standard deviation, range, and the 95% upper confidence limit (UCL) statistics should be included for the sample analytical data for each survey unit without subtracting background. Background reference areas selected may not be appropriate for comparison, so background subtraction should not be done first. Please revise the text to indicate that statistics will be conducted without subtracting background values from measurements.
- 22. Section 6.4.1, Sample Analytical Data, Page 6-6:** A background evaluation should only be performed for naturally occurring radionuclides (i.e., Ra-226). When a background evaluation is performed, all natural decay series should be evaluated for secular equilibrium and expected ratios. Please revise the text to include these details.
- 23. Section 6.6, Background Evaluation, Page 6-7:** The following text in the first paragraph which states “and ubiquitous fallout”, should be deleted. Since the surface soil materials have been mixed and dispersed with subsurface soil materials, no non-natural radionuclide concentrations will have a “background” concentration for comparison. As such, please revise Section 6.6 to remove the phrase “and ubiquitous fallout.”
- 24. Section 6.6.1.1, Sample-specific Background Determination, Page 6-9:** The last sentence of Section 6.6.1.1 should be modified to read, “The sample specific analytical result will be compared to the other nuclides in the decay series to determine if the sample specific result exceeds the expected result with the natural decay series in secular equilibrium.” Please make this change.
- 25. Section 6.6.1.2, NORM Evaluations, Page 6-9:** The text states that a NORM evaluation will be required when a gamma spectroscopy result for a specific laboratory sample analyzed for Ra-226, U-235, or Th-232 exceeds the mean for the background reference area data set by more than the release criteria. It is unclear why U-235 is listed as being identified using gamma spectroscopy only since the detection efficiency of U-235 is low using this method of analysis. If U-235 is a radionuclide of concern for any particular area, the sample should be analyzed by alpha spectroscopy to quantitate U-235. Please revise the Work Plan to require samples being investigated for the presence of U-235 to be analyzed by alpha spectroscopy.

- 26. Table 6-1, Laboratory Alpha Spectroscopy and Emanation, Page 6-9:** The table indicates that if U-235 exceeds the mean for the background reference area by more than the release criteria, alpha spectroscopy analysis will be performed for U-235 and U-238. It is assumed that the concentrations of these two isotopes will be evaluated to determine if they are present in an approximate 1:1 ratio, however, the Work Plan does not include this information. Please revise Section 6.6.1.2 (NORM Evaluations) to include additional detail about how the U-235 and U-238 data will be evaluated to identify whether the results indicate the soil is representative of background or of site contamination. In addition, as previously requested by EPA, please revise the Work Plan to require the reporting of all Uranium isotopes, U-234, U-235, and U-238 as well as thorium isotopes Th-228, Th-230, Th-232, Th-234, and Po-210 for the purposes of NORM evaluations.
- 27. Table 6-1, Laboratory Alpha Spectroscopy and Emanation, Page 6-9:** Table 6-1 indicates that an evaluation of whether elevated levels of Th-232 are due to background or site contamination will include alpha spectroscopy analysis of Th-232 and U-238. It is assumed that the concentrations of these two isotopes will be evaluated to determine if they are present in an approximate 1:1 ratio, however, the text does not explicitly state this. Please revise Section 6.6.1.2 (NORM Evaluations) to provide additional detailed information about how this evaluation will be made. In addition, also revise the Work Plan to include the reporting of all uranium and thorium isotopes reportable by alpha spectroscopy to assist in identifying whether the concentration of radionuclides represents background levels or site contamination.
- 28. Section 6.6.4, Dose and Risk Analysis, Page 6-10:** Section 6.6.4 should include additional detail regarding usage of the EPA PRG calculator for risk analyses. Risk analyses should utilize the EPA PRG calculator for natural decay chain radionuclides and any non-natural radionuclides determined to be present with the required cover in place, inclusive of background. Please revise the text to include this information.
- 29. Section 8.2, Waste Management for Hazardous/Non-Hazardous Sites, Page 8-2:** This section discusses the identification and management of hazardous and/or radioactive wastes but does not discuss requirements that must be met prior to off-site disposal. Please revise the Work Plan to state that the EPA Region 9 off-site rule coordinator will be consulted before disposal of hazardous and/or Low-Level Radioactive Waste (LLRW) soil to ensure that the landfill used for disposal is acceptable.
